## CHAPTER 6. TECHNIQUES OF INTEGRATION Section 6.3. Integration of Rational Functions by Partial Fractions.

In this section, we will develop a way to evaluate integrals of the form  $\int \frac{P(x)}{O(x)} dx$ , where P(x) and Q(x) are polynomials. The idea is to write a rational function as a sum of partial fractions whose denominators are simple linear factors, linear factors of multiplicity m, irreducible factors of degree 2.

Consider the following example.

$$\int \frac{x^3 - 4x - 10}{x^2 - x - 6} \ dx$$

It is clear that a direct substitution will not work. To evaluate a rational integral of the form  $\int \frac{P(x)}{Q(x)} dx$  we perform the following tasks:

- 1. If the degree of P(x) is greater than or equal to the degree of Q(x) then divide P(x) by Q(x) so that  $\frac{P(x)}{Q(x)} = S(x) + \frac{R(x)}{Q(x)}$ .

  2. Factor the denominator of  $\frac{R(x)}{Q(x)}$  as far as possible. Then, the following situations of  $\frac{R(x)}{Q(x)}$  as far as possible.
- tions can occur:
  - The denominator Q(x) is a product of linear factors.  $Q(x) = (a_1x + b_1)(a_2x + b_2)\dots(a_kx + b_k)$ then there exists real numbers  $A_1, A_2, \dots A_k$  such that

$$\frac{R(x)}{Q(x)} = \frac{A_1}{a_1 x + b_1} + \frac{A_2}{a_2 x + b_2} + \dots \frac{A_k}{a_k x + b_k}$$

## Example: Write

$$\frac{x^3 - 4x - 10}{x^2 - x - 6}$$
 as a sum of partial fractions.

$$\frac{x^{3}-4x-10}{x^{2}-x-6} \text{ as a sum of partial fractions.}$$

$$\frac{x^{1}-x-6}{x^{3}+0} = \frac{x^{2}-4x-10}{x^{2}-x-6}$$

$$\frac{x^{2}-4x-10}{x^{2}-x-6} = x+1+\frac{3x-4}{x^{2}-x-6}$$

$$\frac{x^{3}-4x-10}{x^{2}-x-6} = x+1+\frac{3x-4}{x^{2}-x-6}$$

$$\frac{1}{12} = \frac{1}{3} - \frac{1}{4}$$

$$-\frac{x^{2}-4x-10}{x^{2}-x-6} = x+1 + \frac{3x-4}{x^{2}-x-6}$$
\(\frac{1}{12} = \frac{1}{3} - \frac{1}{4}\)

$$\frac{3x_{-4}}{x^{2}-x_{-6}} = \frac{3x_{-4}}{(x_{-3})(x+2)} = \frac{A}{x_{-3}} + \frac{B}{x+2} \quad \text{where } A \notin B \text{ are example.}$$

Find A&B

A A & B
$$\left(\frac{3x-4}{(x-3)(x+2)} = \frac{A}{x-3} + \frac{B}{x+2}\right) (x-3)(x+2)$$

$$3x-4 = A(x+2) + B(x-3)$$

Elimination method:

$$\begin{array}{ccc}
x = -2 & -10 = -5 & \\
B = 2 & \\
x = 3 & 5 = 5 & \\
\hline
A = 1 & \\
\end{array}$$

Identifying toefficient method

initiation method:  

$$x = -2$$
  $-10 = -5B$   
 $B = 2$   
 $x = 3$   $5 = 5A$   
 $3x - 4 = (A + B)x + 2A - 3B$   
 $3x - 4 = (A + B)x + 2A - 3B$   
 $3x - 4 = (A + B)x + 2A - 3B$   
 $3x - 4 = (A + B)x + 2A - 3B$   
 $3x - 4 = (A + B)x + 2A - 3B$   
 $3x - 4 = (A + B)x + 2A - 3B$ 

$$\int \frac{x^{3}-4x-10}{x^{2}-x-6} dx = \int (x+1+\frac{1}{x-3}+\frac{2}{x+2}) dx$$

$$= \frac{x^2}{2} + x + [n|x-3| + 2 |n|x+2| + C$$

ullet The denominator Q(x) is a product of linear factors, some of which are repeated.

If Q(x) contains a factor  $(a_1x+b_1)$  that is repeated m times, then the sum of partial fractions will contain the following

Example: Write 
$$\frac{x-5}{(x^2(x-1)^3(x+3))}$$
 as a sum of partial fractions.  
 $\frac{x-5}{x^2(x-1)^3}$   $\frac{A_1}{(x+3)}$   $\frac{A_2}{x}$   $\frac{B_1}{x^2}$   $\frac{B_2}{x^2}$   $\frac{B_3}{(x-1)^3}$   $\frac{A_1}{(x-1)^3}$   $\frac{A_2}{x}$   $\frac{B_1}{x^2}$   $\frac{A_2}{x^2}$   $\frac{B_1}{x^2}$   $\frac{A_2}{x^2}$   $\frac{B_3}{x^2}$   $\frac{A_1}{x^2}$   $\frac{A_2}{x^2}$   $\frac{A_1}{x^2}$   $\frac{A_1}{x^2}$   $\frac{A_1}{x^2}$   $\frac{A_2}{x^2}$   $\frac{A_1}{x^2}$   $\frac{A_1}{x^2$

## • The denominator Q(x) contains irreducible factors, none of which is repeated.

When is a polynomial of the form  $ax^2 + bx + c$  irreducible?

$$ax^{2}+bx+c=0$$

$$x=-b\pm\sqrt{C^{2}-4ac} \quad discriminant$$

$$0x^{2}+bx+c \quad is irreducible when  $b^{2}-4ac<0$ 

$$y=x^{2}+1>0$$$$

The decomposition of  $\frac{R(x)}{Q(x)}$  will contain terms of the form

$$\frac{Ax+B}{ax^2+bx+c}$$

where A and B are real numbers.

**Example:** Write  $\frac{x^2-2x-1}{(x-1)^2(x^2+1)}$  as a sum of partial fractions, then integrate the function

$$\frac{x^{2}-2x-1}{(x-1)^{2}(x^{2}+1)} = \frac{A}{(x-1)^{2}} + \frac{B}{(x-1)^{2}} + \frac{Cx+D}{x^{2}+1}$$

$$\frac{Cx}{x^{2}+1} + \frac{D}{x^{2}+1}$$
This

this

$$\frac{1}{2} \ln |x^{2}+1| + \ln |x|$$

 $x^{2} - 2x - 1 = A(x-1)(x^{2}+1) + B(x^{2}+1) + (Cx+D)(x-1)$ 

$$x^{2} - 2x - 1 = A(x - 1)(x^{2} + 1) + B(x^{2} + 1) + (Cx + D)(x - 1)^{2}$$
 $x = 1 - 2 = 2B \implies B = -1$

## Rationalizing Substitutions.

Some integrals involving radicals can be treated like integrals of rational functions by letting  $u = \sqrt[n]{g(x)}$ .

Example: Evaluate the integral.

Rationalizing substitution: 
$$u=\sqrt{x}$$
 =>  $x=u^2$ 

$$dx = 2udu$$

$$\int \frac{u}{u^2+1} (2u du) = 2 \int \frac{u^2}{u^2+1} du$$

Divide:  $\frac{u^2}{u^2+1} = \frac{u^2+(-1)}{u^2+1} = 1 - \frac{1}{u^2+1}$ 

$$2 \int \frac{u^2}{u^2+1} du = 2 \int (1 - \frac{1}{u^2+1}) du = 2 \int u - \tan^{-1}u du$$

$$\int \frac{\sqrt{x}}{x+1} dx = 2 (\sqrt{x} - \tan^{-1}(\sqrt{x})) + C$$

Additional example:

$$\int \frac{x^{5} + x - 1}{x^{3} + 1} dx$$

$$x^{3} + 1 \int x^{5} + 0x^{4} + 0x^{3} + 0x^{2} + x - 1$$

$$- (x^{5} + x^{2})$$

$$- x^{2} + x - 1$$

$$\int (x^{2} + -\frac{x^{2} + x - 1}{x^{3} + 1}) dx = \frac{x^{3}}{3} + \int \frac{-x^{2} + x - 1}{x^{3} + 1} dx$$

$$- \frac{x^{2} + x - 1}{x^{3} + 1} = \frac{-x^{2} + x - 1}{(x + 1)(x^{2} - x + 1)} = -\frac{1}{x + 1}$$

$$a^{3} + b^{3} = (a + b)(a^{2} - ab + b^{2})$$

$$a^{3} + \int \frac{-1}{x + 1} dx = \frac{x^{3}}{3} - \ln|x + 1| + C$$
